FOURIER METHODS FOR ESTIMATING MIXING DENSITIES AND DISTRIBUTIONS

BY CUN-HUI ZHANG

State University of New York at Stony Brook and Rutgers University

Let \( X_1, X_2, \ldots \) be iid observations from a mixture density \( f(x) = \int f(x|\theta) \, dG(\theta) \), where \( f(x|\theta) \) is a known parametric family of density functions and \( G \) is an unknown distribution function. This paper concerns estimating the mixing density \( g = G' \) and the mixing distribution \( G \). Fourier methods are used to derive kernel estimators, upper bounds for their rates of convergence and lower bounds for the optimal rate of convergence. Sufficient conditions are given under which the kernel estimators are asymptotically normal. Our estimators achieve the optimal rate of convergence \((\log n)^{-1/2}\) for the normal family and \((\log n)^{-1}\) for the Cauchy family.

1. Introduction. Let \( \{f(x|\theta), \, \theta \in \Theta\} \) be a known parametric family of probability density functions with respect to a \( \sigma \)-finite measure \( \mu \). The density function \( f(x) \) of a random variable \( X \) belongs to a mixture model if

\[
f(x) = f(x; G) = \int f(x|\theta) \, dG(\theta),
\]

where \( G \) is a probability distribution function. This paper concerns estimating the mixing density function \( g = dG/d\theta \) and the mixing distribution function \( G \) based on iid observations \( X_1, \ldots, X_n \) with common marginal density \( f(x) \).

We consider kernel estimators for mixing densities and distributions. A sequence of functions \( K_n(x) \) is a kernel for a functional \( \lambda = \lambda_G \) of \( G \) if \( \lim_n E_G K_n(X) = \lambda_G \) under suitable conditions. A kernel estimator for \( \lambda \) is basically the average of iid random variables \( n^{-1} \sum_{j=1}^n K_n(X_j) \).

**Example 1** (Normal). Suppose that \( f(x|\theta) = \varphi(x - \theta), \varphi(x) = (2\pi)^{-1/2}e^{-x^2/2} \). Then \( e^{it^2/2}Ee^{itX} \) is the characteristic function of \( G \), so that a kernel for the mixing density \( g = G' \) can be obtained by making use of the Fourier inversion formula.

In Section 2 Fourier methods are used to derive kernel estimators for mixing densities and upper bounds for their rates of convergence. In Section 3 kernels for mixing distributions are obtained by integrating kernels for mixing densities. Asymptotical normality of the kernel estimators is obtained under conditions on the growth of the second moment of the kernels.

Key words and phrases. Mixing distribution, kernel estimation, contiguity, Fourier transformation.

806
Lower bounds for the optimal rate of convergence are given in Section 4. Let $g_n = G_n'$ be a sequence of mixing density functions such that the sequences $(\prod_{j=1}^{n} f(x_j; G_n))$ and $(\prod_{j=1}^{n} f(x_j; G))$ are contiguous. Then the order of $g_n - g$, $g = G'$, can serve as a lower bound for the rate of convergence for estimating the mixing density. Our problem is to find “bad” contiguous sequences and quantify the rate of $g_n - g$. To motivate our method, let us consider

**Example 1 (Normal, continuation).** Let $g_0(\theta) = G_0'(\theta) = \varphi((\theta - \mu)/\sigma)/\sigma$ be a normal mixing density. Then $f(x|\theta)g_0(\theta)/f(x; G_0)$ is a normal density (in $\theta$) with variance $\sigma^2/(1 + \sigma^2)$ for every fixed $x$, so that

$$
\left| \int \exp[id_n \theta] f(x|\theta)g_0(\theta) \, d\theta \right| = \exp[-d_n^2 \sigma^2/(2(1 + \sigma^2))] \cdot f(x; G_0).
$$

Let $g_n = g_0 + (w/d_n)(\cos(d_n \theta) - e_n)g_0$, where $0 < w < 1/2$, $d_n^2 \sigma^2/(1 + \sigma^2) = \log n$ and the constant $e_n$ is chosen such that $g_n$ is a probability density function. Then it can be shown that $|f(x; G_n)/f(x; G_0) - 1| \leq 1/\sqrt{n}$, so that the sequences $(\prod_{j=1}^{n} f(x_j; G_n))$ and $(\prod_{j=1}^{n} f(x_j; G))$ are contiguous. Therefore, $1/d_n \sim (\log n)^{-1/2}$, the order of $g_n - g_0$, is a lower bound for the optimal rate of convergence for the class of $G$ with a bounded second derivative, if we are interested in estimating mixing densities. This idea of using Fourier methods to construct contiguous sequences will be developed in detail under a smoother condition on the family $f(x|\theta)$.

We shall consider location families

$$
f(x|\theta) = f_0(x - \theta), \quad \mu(dx) = dx, \quad \theta \in (-\infty, \infty),
$$

(2)\[ f_0^*(t) = \int e^{itx}f_0(x) \, dx \neq 0, \quad \forall t, \]

throughout the paper. Some of our arguments can be extended to exponential families, but these extensions are incomplete and omitted to save space. For the location case, both the rate of convergence for our kernel estimators and the lower bound for the optimal rate of convergence are essentially given in terms of the tail of the characteristic function $f_0^*$ of $f_0$. The rates are slower for $f_0^*$ with thinner tails. Since smooth density functions have characteristic functions with thin tails, the optimal rates of convergence are related to the smoothness of the family $f(x|\theta)$ with slower rates corresponding to smoother families. See the discussions after Theorems 1 and 6. For the sake of space, we only consider the rates for the largest class of $G$ with minimum smoothness conditions to which our methods are directly applicable. Three examples, the normal, Cauchy and double exponential cases, are considered in each section. The rates for these examples are summarized in Table 1. Our kernel estimators have the optimal rate of convergence $(\log n)^{-1/2}$ for the normal case and $(\log n)^{-1}$ for the Cauchy case.

Problems related to mixture models were proposed by Robbins (1951, 1955) in connection with the empirical Bayes approach to compound decision prob-
lems, by Kiefer and Wolfowitz (1956) in connection with estimating an unknown parameter in the presence of infinitely many nuisance parameters and by many others in various contexts. Estimating mixing densities and/or mixing distributions has been studied by Deely and Kruse (1968), Jewell (1982), Kiefer and Wolfowitz (1956), Laird (1978), Lindsay (1983a, b), Robbins (1950) and Rolph (1968) among others. Various consistent estimators have been proposed, but their rates of convergence and asymptotic distributions are unknown. Recently, Edelman (1988) proposed an estimator for the “empirical” mixing distribution function for the normal case and gave an upper bound \((\log n)^{-1/4}\) for its rate of convergence. The relationship between a part of this work and some of Edelman’s results is discussed in Section 3. Estimating mixing densities and the optimal rate of convergence were also studied independently by Stefanski and Carroll (1988) and Carroll and Hall (1988).

Throughout this paper we denote by \(P = P_G\) and \(E = E_G\) the probability and expectation corresponding to \(G\), respectively, by \(H^*\) the characteristic function of any distribution function \(H\) and by \(h^*\) the Fourier transformation of any integrable function \(h\), so that \(h^*(t) = \int e^{itx} h(x) \, dx\) for any \(\int |h(x)| \, dx < \infty\).

2. Kernel estimation for mixing densities. In this section we give kernel estimators for mixing density functions and their rates of convergence in the \(L^2\) norm \(\|h\| = \left( \int |h(x)|^2 \, dx \right)^{1/2}\) and in the mean square error at fixed \(\theta = a\). The asymptotic normality at fixed \(\theta = a\) is also given under a condition on the growth of the variance of the kernel.

A sequence of functions \(K_n(x, a)\) is a kernel for \(g(\theta) = G'(\theta) = dG/d\theta\) at \(\theta = a\) if

\[
\int_{a-\delta}^{a+\delta} K_n(x, a) f(x|\theta) \mu(dx) \, d\theta \to 1 \quad \text{as} \ n \to \infty, \forall 0 < \delta < \infty.
\]

Under certain regularity conditions on \(G\), (3) implies that \(EK_n(X, a) \to g(a)\), so that the statistic

\[
\hat{g}_n(a) = \left[ n^{-1} \sum_{j=1}^{n} K_n(X_j, a) \right]^+, \quad x^+ = \max(x, 0),
\]
can be used to estimate \( g(a) \). As \( \hat{g}_n(a) \) is the nonnegative part of a sum of iid random variables, we can bound the mean square error \( E[\hat{g}_n(a) - g(a)]^2 \) (and therefore the rate of convergence) if we can find upper bounds for \( \text{Var}(K_n(X,a)) \) and \( \|EK_n(X,a) - g(a)\| \). It is clear by (3) that the choice of \( K_n(x,a) \) depends on the family \( f(x|\theta) \) and the measure \( \mu \).

Consider the location case (2). Similar to the normal case, Example 1 in Section 1, the expectation of the random variable \( e^{itX}f_0^*\) is the characteristic function \( g^*(t) \) of \( G \). By the Fourier inversion formula,

\[
(2\pi)^{-1} \int k^*(t/c) e^{-ita} g^*(t) \, dt \to g(a) \quad \text{as } c \to \infty
\]

for any smooth integrable function \( k \) with \( k^*(0) = 1 \), so that we can define a kernel by

\[
K_n(x,a) = (2\pi)^{-1} \int \mathbb{R}\{k^*(t/c_n) e^{it(x-a)}/f_0^*(t)\} \, dt, \quad 0 < c_n \uparrow \infty,
\]

where \( \mathbb{R}(z) \) is the real part of \( z \) and \( k(x) \) is a probability density function such that

\[
k(x) = k(-x), \quad \int x^2 k(x) \, dx < \infty, \quad \int |xk'(x)| \, dx < \infty,
\]

\[
k^*(t) = 0, \quad \forall |t| > 1.
\]

Since \( k^*(t/c_n) \) is the Fourier transformation of \( c_n k(c_n x) \),

\[
\int K_n(x,a) f(x|\theta) \mu(dx)
\]

\[
= \mathbb{R}\left\{ \int \int (2\pi f_0^*(t))^{-1} k^*(t/c_n) e^{it(x-a)} f_0(x - \theta) \, dx \, dt \right\}
\]

\[
= (2\pi)^{-1} \mathbb{R}\left\{ \int k^*(t/c_n) e^{it(\theta - a)} \, dt \right\} = c_n k(c_n(a - \theta)),
\]

which implies (3). Hence, \( K_n \) is a kernel. There are many density functions satisfying (6). For example, \( k(x) = (\pi/6)(2/x) \sin(x/4)^4 \), whose characteristic function is proportional to the density function of the average of four independent unif\((-1,1)\) random variables with \( k^*(0) = 1 \). In the sequel we shall always use the notation

\[
C_1 = \int |x| k(x) \, dx, \quad C_2 = \int x^2 k(x) \, dx, \quad C_3 = \int |k^*(t)|^2 \, dt,
\]

\[
e(\chi) = \int_{\chi} yk(y) \, dy + \sup_{y \geq \chi} y^2 k(y).
\]

The constants \( c_n \) in (5) should be chosen to "balance" the bias and the variance of the kernel estimators. In view of (7) we shall choose large \( c_n \) to ensure small bias \( EK_n(X,a) - g(a) \). On the other hand, if \( c_n \) is too large, then by (5) the variance \( \text{Var}(K_n(X,a)) \) is hard to control, since \( f_0^*(t) \to 0 \) as
\( t \to \infty \). The properties of our kernel estimators are studied in Theorems 1 and 2, where the constants \( c_n \) and upper bounds for the risks are expressed in terms of the tail of \( |f_0^s(t)| \). Let us first consider the \( L^2 \) norm. Define

\[
\mathcal{S}_1 = \mathcal{S}(M_1) = \{ G : G \text{ has a density } g \text{ with } \|tg^*(t)\| \leq M_1 \}.
\]

**Theorem 1.** Let the estimator \( \hat{g}_n \) for the mixing density \( g = G^* \) be defined by (4) with the kernel \( K_n(x, a) \) given by (5) and constants \( c_n \) satisfying

\[
1/n \leq c_0|f_0^*(c_n)|^2/c_n^3, \quad c_0 < \infty, \quad |f_0^*(c_n)| = \min_{|t| \leq c_n} |f_0^*(t)|.
\]

Then

\[
\lim_{n \to \infty} E\| \hat{g}_n - g \|^2 = 0, \quad \forall G \text{ with a density } g \text{ such that } \|g\| < \infty,
\]

\[
\sup_{G \in \mathcal{S}(M_1)} c_n^2E_G\| \hat{g}_n - g \|^2 \leq \left[ c_0C_3 + (M_1C_1)^2 \right]/(2\pi), \quad \forall n \geq 1.
\]

Clearly, the smoother the density \( f_0 \) is, the faster \( f_0^*(t) \) vanishes as \( t \to \infty \) and by (9) the slower the upper bound \( c_n^{-2}O(1) \) in (11) for the risk \( E_G\| \hat{g}_n - g \|^2 \) converges to 0. By (9) we see that the constants \( c_n \) are of polynomial order in \( n \) (Example 3) if \( f_0^*(t) \) is of polynomial order in \( t \) for large \( t \) and \( c_n \) are of logarithmic order (Examples 1 and 2) if \( f_0^*(t) \) is of exponential order. As far as the rate of convergence is concerned, the choice of \( k(\cdot) \) and \( c_0 \) does not matter. Of course, one can choose them to minimize the right-hand side of (11). But this requires the knowledge of \( M_1 \) or a good estimation of \( \|tg^*(t)\| \). We shall not discuss the problem of estimating the "best" \( k(\cdot) \) and/or \( c_0 \) here.

**Example 1** (Normal, continuation). Since \( f(x|\theta) \sim N(\theta, 1) \), we have \( f_0^*(t) = e^{-t^2/2} \), so that

\[
K_n(x, a) = (2\pi)^{-1}\int \cos(t(x-a))e^{t^2/2k^*(t/c_n)} dt.
\]

Choose, \( c_n = \sqrt{\alpha \log n} \), \( 0 < \alpha < 1 \). It follows that

\[
\sup_{G \in \mathcal{S}(M_1)} (\log n)E_G\| \hat{g}_n - g \|^2 \leq \left[ C_3\sqrt{\alpha \log n}^{-1}(\log n)^{3/2} + C_1^2M_1^2/\alpha \right]/(2\pi).
\]

**Example 2** (Cauchy). Suppose \( f_0(x) = (1 + x^2)^{-1}/\pi \). Let \( c_n = \alpha \log n \), \( 0 < \alpha < 1 \). Then

\[
\sup_{G \in \mathcal{S}(M_1)} (\log n)^2E_G\| \hat{g}_n - g \|^2 \leq \left[ C_3\alpha n^{(1/2)}(\log n)^3 + C_1^2M_1^2/\alpha^2 \right]/(2\pi).
\]

**Example 3** (Double exponential). Suppose \( f_0(x) = e^{-|x|}/2 \). Let \( c_n = \alpha n^{1/7} \), \( 0 < \alpha \). Then

\[
\lim_{n \to \infty} \sup_{G \in \mathcal{S}(M_1)} n^{2/7}E_G\| \hat{g}_n - g \|^2 \leq \left[ \alpha^6C_3 + C_1^2M_1^2/\alpha^2 \right]/(2\pi).
\]
PROOF OF THEOREM 1. Since $K_n(x, \cdot)$ is the real part of the Fourier inversion of $k^*(t/c_n)e^{itx}/f^*_0(t)$ for fixed $x$, it follows from the Plancherel identity that

$$2\pi E \int K_n^2(X, \theta) \, d\theta / \leq \int |k^*(t/c_n)/f^*_0(t)|^2 \, dt/n$$

$$\leq \left[ c_n \int |k^*(t)|^2 \, dt / \left[ n |f^*_0(c_n)|^2 \right] \right]$$

$$= c_n C_3 / \left[ n |f^*_0(c_n)|^2 \right].$$

By (7) $E K_n(X, \cdot)$ has the Fourier transformation $k^*(t/c_n)g^*(t)$, so that for $\|g\| < \infty$,

$$2\pi \int |EK_n(X, \theta) - g(\theta)|^2 \, d\theta = \int |k^*(t/c_n)g^*(t) - g^*(t)|^2 \, dt \to 0.$$

Since by (4)

$$E \|\hat{g}_n - g\|^2 \leq E \|K_n(X, \cdot)\|^2/n + \|EK_n(X, \cdot) - g\|^2,$$

we have (10) by adding the two inequalities together. For (11) we have

$$2\pi c_n^2 E \|\hat{g}_n - g\|^2 \leq c_0 C_3 + c_n^2 \int |k^*(t/c_n)g^*(t) - g^*(t)|^2 \, dt$$

$$\leq c_0 C_3 + C_2 \int |tg^*(t)|^2 \, dt.$$ \hfill $\square$

Now consider a fixed point $\theta = a$. We shall give the asymptotic normality for our estimators as well as upper bounds for their rate of convergence. A mixing density $g$ satisfies the Lipschitz condition at $\theta = a$ if

(12) $|g(a + \theta) - g(a)| \leq M_2|\theta|$, \quad $\forall |\theta| \leq \delta$.

Define

$$\mathcal{I}_2 = \mathcal{I}_2(a, \delta, M_2)$$

(13) $= \{G: g = G' \text{ exists in } [a - \delta, a + \delta] \text{ and } (12) \text{ holds} \}.$

THEOREM 2. Let the estimator $\hat{g}_n$ be as in Theorem 1 such that (5) and (9) hold.

(i) If $g = G'$ exists at $\theta = a$, the $\lim_n E|\hat{g}_n(a) - g(a)|^2 = 0.$

(ii) For any $n \geq 1$,

$$\sup_{G \in \mathcal{I}_2(a, \delta, M_2)} c_n^2 E|\hat{g}_n(a) - g(a)|^2$$

(14) $\leq c_0 \frac{2\pi^2}{2\pi^2} \int |f^*_0(t)| \, dt + [\varepsilon(c_n \delta)(\delta^{-2} + M_2) + M_2 C_1]^2.$
Suppose that \( \lim_{n \to \infty} EK_n^2(X, a) = \infty \),

\[
\lim_{n \to \infty} \sup_{x} |K_n(x, a)/\sqrt{n}EK_n^2(X, a)| = 0, \quad \liminf_{n \to \infty} c_n^2 EK_n^2(X, a)/n > 0.
\]

Let \( \hat{\sigma}_n^2 = \hat{\sigma}_n^2(a) = \sum_{j=1}^{n} K_n^2(X_j, a)/n \). If \( g(a) \) exists, then

\[
\sqrt{n} \left( \hat{g}_n(a) - g(a) \right)/\hat{\sigma}_n \to \mathcal{D} N(0, 1) \quad \text{if} \quad 0 < g(a) < \infty,
\]

\[
\sqrt{n} \hat{g}_n(a)/\hat{\sigma}_n \to \mathcal{D} [N(0, 1)]^+ \quad \text{if} \quad g(a) = 0.
\]

(iv) Suppose that \( g^*(a) \) exists and \( \lim_{x \to \infty} x^3k(x) = 0 \). If

\[
\lim_{n \to \infty} c_n^2/n |f_0^*(c_n)|^2 = 0,
\]

then

\[
\lim_{n \to \infty} c_n^2(\hat{g}_n(a) - g(a)) = g^*(a) \int x^3k(x) \, dx/2, \quad \text{in mean square}.
\]

**Remarks.** (1) If \( \int |f_0^*(t)| \, dt = \infty \), then the first term on the right-hand side of (14) can be replaced by \( c_0 \int_{-\infty}^{\infty} |f_0^*(t)| \, dt/\sqrt{2\pi} \). (2) Since \( x^3k(x) \) has a bounded Fourier transformation with compact support, \( \lim_{x \to \infty} \varepsilon(x) = 0 \). (3) The inequality (14) is still meaningful when \( \delta = \infty \).

Condition (15) simply ensures that the bias of the kernel estimator has a smaller order than the standard deviation. In this case part (iii) shall be used to obtain the asymptotic normality (Example 3). If the standard deviation is of smaller order than the bias, then the limiting distribution is degenerate and part (iv) shall be used (Examples 1 and 2).

**Example 1** (Normal, continuation). Since \( \int |f_0^*(t)| \, dt = \sqrt{2\pi} \),

\[
\sup_{G \in \mathcal{G}(a, \delta, M_2)} (\log n) E_G|\hat{g}_n(a) - g(a)|^2
\]

\[
\leq \frac{\alpha (\log n)^{3/2}}{\pi \sqrt{2\pi} n^{1-\alpha}} + \frac{1}{\alpha} \left[ \varepsilon(\delta \sqrt{\alpha \log n})(\delta^{-2} + M_2) + C_1 M_2 \right]^2.
\]

If \( g^*(a) \) exists, then

\[
\lim_{n \to \infty} (\log n)(\hat{g}_n(a) - g(a)) = g^*(a) C_2/(2\alpha), \quad \text{in mean square}.
\]

**Example 2** (Cauchy, continuation). Since \( \int |f_0^*(t)| \, dt = 2 \),

\[
\sup_{G \in \mathcal{G}(a, \delta, M_2)} (\log n)^2 E_G|\hat{g}_n(a) - g(a)|^2
\]

\[
\leq \frac{\alpha (\log n)^3}{\pi^2 n^{1-\alpha}} + \frac{1}{\alpha^2} \left[ \varepsilon(\delta \alpha \log n)(\delta^{-2} + M_2) + C_1 M_2 \right]^2.
\]
If \( g^*(a) \) exists, then
\[
\lim_{n \to \infty} (\log n)^2 (\hat{g}_n(a) - g(a)) = g^*(a) C_2 / (2\alpha^2), \quad \text{in mean square.}
\]

**Example 3** (Double exponential, continuation). Since \( |f_0^*(t)| dt = \pi \),
\[
\lim_{n \to \infty} \sup_{G \in \mathcal{G}(a, \delta, M_2)} n^{2/7} E_G |\hat{g}_n(a) - g(a)|^2 \leq \alpha^5 / (2\pi) + C_1^2 M_2^2 / \alpha^2.
\]
Let \( \hat{\Lambda}_n^2 = \sum_{j=1}^n K_n^2(X_j, a)/n \). If \( g'(a) \) exists, then (15) holds by Lemma 1 in the Appendix, so that
\[
\sqrt{n} (\hat{g}_n(a) - g(a)) / \hat{\Lambda}_n \to_{\mathbb{P}} N(0, 1) \quad \text{if } g(a) > 0,
\]
\[
\sqrt{n} \hat{g}_n(a) / \hat{\Lambda}_n \to_{\mathbb{P}} [N(0, 1)]^+ \quad \text{if } g(a) = 0.
\]

**Proof of Theorem 2.** (i) To bound the variance at \( \theta = a \), we have by (5) and (9)
\[
\text{Var}(K_n(X, a)) \leq EK_n^2(X, a)
\]
\[
\leq (2\pi)^{-2} \int_{-c_n}^{c_n} \int_{-c_n}^{c_n} \left[ k^*(t/c_n) / f_0^*(t) \right] \left[ k^*(s/c_n) / f_0^*(s) \right] \times \text{Exp} \left[ i(t-s)(X-a) \right] ds \, dt
\]
\[
\leq (2\pi)^{-2} \int_{-c_n}^{c_n} \int_{-c_n}^{c_n} \left| f_0^*(c_n) \right|^{-2} \left| f_0^*(t-s) \right| ds \, dt
\]
\[
\leq (2\pi)^{-2} 2c_n \left| f_0^*(c_n) \right|^{-2} \int_{-2c_n}^{2c_n} \left| f_0^*(u) \right| du.
\]

It follows from (7) that
\[
EK_n(X, a) = - \int c_n k(x) \, dG(a - x/c_n)
\]
\[
= \int c_n \left[ G(a - x/c_n) - G(a) \right] k'(x) \, dx
\]
\[
= -g(a) \int xk'(x) \, dx + O(1) \int_{-\infty}^{\infty} xk'(x) \, dx + o(1) \int xk'(x) \, dx,
\]
which implies the mean square consistency by (4) and (16), since \(-\int xk'(x) \, dx = \int k(x) \, dx = 1\).

(ii) Let \( \varepsilon_1(x) = \sup_{y \geq x} y^2 k(y) \) and \( \varepsilon_2(x) = \int_x^{\infty} yk(y) \, dy \). By (7) and (12)
\[
c_n |EK_n(X, a) - g(a)| \leq c_n \int_{-a-\delta}^{a+\delta} c_n k(c_n(a - \theta)) g(\theta) \, d\theta - g(a)
\]
\[
\leq c_n \int_{-c_n\delta}^{c_n\delta} k(x) [g(a + x/c_n) - g(a)] \, dx
\]
\[
+ \varepsilon_1(c_n \delta) / \delta^2 + 2g(a) \varepsilon_2(c_n \delta) / \delta
\]
\[
\leq \varepsilon_1(c_n \delta) / \delta^2 + 2g(a) \varepsilon_2(c_n \delta) / \delta + M_2 C_1.
\]
By the Lipschitz condition,
\[
1 \geq \int_{a - \delta}^{a + \delta} g(\theta) \, d\theta \geq \int_{a - \delta}^{a + \delta} \left[ g(a) - M_2|\theta - a| \right] \, d\theta = 2\delta g(a) - M_2\delta^2.
\]
Hence, we have part (ii) by (16) and (17).

(iii) Basically the asymptotic normality follows from the Lindeberg central limit theorem. Since \( EK_n(X, a) \to g(a) \) and \( EK_n^2(X, a) \to \infty \), \( \text{Var}(K_n(X, a)) = (1 + o(1))EK_n^2(X, a) \), so that by (15)
\[
\varepsilon_n = \max_x |K_n(x, a)| \sqrt{n\sigma_n^2} = (1 + o(1)) \max_x |K_n(x, a)| \sqrt{\text{Var}(K_n(X, a))} = o(1),
\]
where \( \sigma_n^2 = \text{Var}(K_n(X, a)) \). Let \( Y_{n,j} = [K_n(X_j, a) - EK_n(X, a)]/\sqrt{n\sigma_n^2} \). Then \( P[|Y_{n,j}| \leq 2\varepsilon_n] = 1 \), which implies by the Lindeberg central limit theorem that
\[
\sqrt{n} \left[ \sum_{j=1}^{n-1} K_n(X_j, a) - EK_n(X, a) \right]/\sigma_n = \sum_{j=1}^{n} Y_{n,j} \to_{\mathcal{D}} N(0, 1).
\]
Taking the Taylor expansion of \( g(a + x/c_n) - g(a) \) at the last step of (17), we have by (15)
\[
\sqrt{n} \left[ EK_n(X, a) - g(a) \right]/\sigma_n = O(1) c_n EK_n(X, a) - g(a) = o(1).
\]
Since
\[
P[\sum_{j=1}^{n-1} K_n(X_j, a) = \hat{g}_n(a)] \to 1 \quad \text{for } g(a) > 0
\]
and \( P[\sum_{j=1}^{n-1} K_n(X_j, a) < 0] \to 1/2 \) for \( g(a) = 0 \),
\[
\sqrt{n} \left( \hat{g}_n(a) - g(a) \right)/\sigma_n \to_{\mathcal{D}} N(0, 1) \quad \text{if } 0 < g(a) < \infty,
\]
\[
\sqrt{n} \left( \hat{g}_n(a) - g(a) \right)/\sigma_n \to_{\mathcal{D}} [N(0, 1)]^+ \quad \text{if } g(a) = 0.
\]
It follows from (18) that
\[
E[\hat{\sigma}_n^2/\sigma_n^2 - 1]^2 \leq (1 + o(1)) EK_n^4(X, a)/(n\sigma_n^4)
\leq (1 + o(1)) \varepsilon_n^2 EK_n^2(X, a)/\sigma_n^2 = o(1).
\]
Hence, \( \hat{\sigma}_n^2/\sigma_n^2 \to 1 \) in probability and part (iii) follows the Slutsky theorem.

(iv) Taking further Taylor expansions of \( g(a + x/c_n) - g(a) \) in (17), we have part (iv) by (16). \( \square \)

3. Estimating mixing distributions. Let the kernel be the same as in Section 2,

\[
K_n(x, a) = (2\pi)^{-1} \int \mathbb{R} [k^*(t/c_n)e^{i(x-a)t}/f_0^*(t)] \, dt, \quad 0 < c_n \uparrow \infty,
\]
with a density function \( k \) such that (6) holds. We shall use the integration \( \int_{a}^{a_{\infty}} K_n(x, \theta) \, d\theta \) as our kernel for the mixing distribution and the statistic
\[
\hat{G}_n(a) = \min \{ (\bar{G}_n(a))^+, 1 \}, \quad \bar{G}_n(a) = \int_{a_{\infty}}^{a} n^{-1} \sum_{j=1}^{n} K_n(X_j, \theta) \, d\theta,
\]
as our estimation for $G(a)$. In this section we study the integrability of the kernel (19) and the asymptotics of $\hat{G}_n$ for the location case (2).

Let $H(\cdot)$ be a distribution function such that $\int_0^1 |1 - H^*(t)|t^{-1} dt + \int_1^\infty |H^*(t)|t^{-1} dt < \infty$. Assume that $\int_0^1 |1 - f_0^*(t)|t^{-1} dt < \infty$. Then
\[
\left| \frac{k^*(t/c_n)e^{itx} - f_0^*(t)H^*(t)}{ift_0^*(t)} \right| dt < \infty,
\]
so that we can define
\[
J_n(x, a) = H(a) - \frac{1}{2\pi} \int e^{-ita} \frac{k^*(t/c_n)e^{itx} - f_0^*(t)H^*(t)}{ift_0^*(t)} dt.
\]

By the Riemann–Lebesgue lemma
\[
\lim_{a \to -\infty} J_n(x, a) = 0 \quad \text{and} \quad \lim_{a \to \infty} J_n(x, a) = 1.
\]

It follows from the Fourier inversion formula that
\[
\int_a^b K_n(x, \theta) d\theta = \mathbb{R}\{J_n(x, b) - J_n(x, a)\},
\]
which implies that $K_n(x, \cdot)$ is Riemann integrable and $\int_{-\infty}^\infty K_n(x, \theta) d\theta = \mathbb{R}\{J_n(x, a)\}$. Hence, letting $F_n(x)$ be the ECDF of $X_1, \ldots, X_n$, we have
\[
\hat{G}_n(a) = \mathbb{R}\left\{ \frac{1}{n} \sum_{j=1}^n J_n(X_j, a) \right\}
\]
\[
= H(a) - \frac{1}{2\pi} \int \mathbb{R}\left\{ e^{-ita} \frac{k^*(t/c_n)F_n^*(t) - f_0^*(t)H^*(t)}{ift_0^*(t)} \right\} dt.
\]

We first consider the $L^2$ loss. The following theorem is proved in the Appendix.

**Theorem 3.** Assume that $\int |x|f_0(x) dx < \infty$. Let $\hat{G}_n$ be defined by (20) with the kernel in (19).

(i) Let $c_n$ be such that $1/n \leq c_0 |f_0^*(c_n)|^2/c_n$, $|f_0^*(c_n)| = \min_{|t| \leq c_n} |f_0^*(t)|$ and $c_n \uparrow \infty$. Then
\[
c_n E\|\hat{G}_n - G\|^2 \leq c_0 \int F_0(x)(1 - F_0(x)) dx + \frac{1 + C_1^2}{\pi}
\]
\[
+ \frac{c_n}{n} \int G(\theta)(1 - G(\theta)) d\theta,
\]
where $F_0(x) = \int_{-\infty}^x f_0(y) dy$. 
(ii) Let \( c_n \) be such that \( 1/n \leq c_0 |f_0^*(c_n)|^2/c_n^2 \), \( |f_0^*(c_n)| = \min_{|t| \leq c_n} |f_0^*(t)| \) and \( c_n \uparrow \infty \). Then

\[
c_n^2 E_G \left\| \hat{G}_n - G \right\|^2 \leq c_0 \int F_0(x)(1 - F_0(x)) \, dx + \frac{C^2 \left\| G^*(t) \right\|^2}{2\pi} + \frac{c_n^2}{n} \int G(\theta)(1 - G(\theta)) \, d\theta.
\]
(24)

**Remark.** \( \int F_0(x)(1 - F_0(x)) \, dx < \infty \) if and only if \( |x| f_0^*(x) \, dx < \infty \).

Let \((X_i, \theta_i)\) be iid random vectors such that \( X_i|\theta_i \sim N(\theta_i, 1) \) and \( \theta_i \sim G \). Choose \( c_n = \sqrt{\alpha \log n} \). Then our argument in the proof shows that

\[
\sqrt{\log n} E_G \left\| \hat{G}_n - G \right\|^2 \leq n^{\alpha - 1} \sqrt{\log n} \left/ \sqrt{\pi} \right. + (1 + C^2)/\sqrt{\pi} \alpha,
\]
(25)

\[
(\log n) E_G \left\| \hat{G}_n - G \right\|^2 \leq n^{\alpha - 1} \log n \, / \sqrt{\pi} + C^2 \left\| G^*(t) \right\|^2 / (2\pi \alpha),
\]
where \( G_n \) is the ECDF of \( \theta_1, \ldots, \theta_n \). The upper bound of Edelman (1988) for estimating \( G_n \) in the normal case is comparable to (25). The quantity \( \int G(\theta) \times (1 - G(\theta)) \, d\theta / n = E\left\| G_n - G \right\|^2 \) in (23) and (24) is the risk of estimating \( G \) by the ECDF \( G_n \) based on the extra knowledge of \( \theta_1, \ldots, \theta_n \). Given the observations \( X_1, \ldots, X_n \), the estimator \( \hat{G}_n \) is not necessarily a distribution function. However, it can be shown that we can always construct a distribution function \( \hat{G}_n^0 \) based on \( \hat{G}_n \) such that \( \left\| \hat{G}_n^0 - H \right\| \leq \left\| \hat{G}_n - H \right\| \) for any distribution function \( H \).

Let us consider a fixed point \( \theta = a \). Under certain moment conditions on \( X \),

\[
EJ_n(X, a) = H(a) - \frac{1}{2\pi} \int e^{-ita} k^*(t/c_n) G^*(t) - H^*(t) \, dt.
\]

Since \( H \) is arbitrary, we can take \( H^* = (k^*(t/c_n)G^*(t), \) which implies that

\[
EJ_n(X, a) = \int G(\theta)c_n k(c_n(a - \theta)) \, d\theta.
\]
(26)

By (6) \( k(x) = k(-x) \) and the right-hand side of (26) converges to

\[
G(a) = \left[ G(a +) + G(a -) \right] / 2,
\]
(27)

which equals to \( G(a) \) if \( G \) is continuous at \( a \). Theorem 4 is also proved in the Appendix.

**Theorem 4.** Assume that \( E(\log(1 + |X|))^2 < \infty \) and \( G \) satisfies the Lipschitz condition

\[
\left| \frac{G(a + \theta) + G(a - \theta)}{2} - G(a) \right| \leq |\theta|M_3 < \infty, \quad \forall 0 < \theta < \delta.
\]
(28)
Choose \( c_n \) such that \( 1/n \leq c_0|f_0^*(c_n)|^2/[c_n \log^+ c_n]^2, \ |f_0^*(c_n)| = \min_{|t| \leq c_n}|f_0^*(t)| \) and \( c_n \uparrow \infty \). Then

\[
\limsup_{n \to \infty} c_n^2 E_G|\hat{G}_n(a) - G(a)|^2 \leq c_0(2/\pi)^4 + M_3^2 C_1^2.
\]

**Example 1** (Normal, continuation). Let \( H(\cdot) \sim N(a, 1) \). Then

\[
\mathbb{R}\{J_n(x, a)\} = 1/2 - (2\pi)^{-1} \int t^{-1} \sin(t(x - a))k^*(t/c_n)e^{t^2/2} dt.
\]

Since \( \int F_0(x)(1 - F_0(x)) dt = 1/\sqrt{\pi} \), by Theorems 3 and 4 we have

\[
\sqrt{\log n} E_G\|\hat{G}_n - G\|^2 \leq \frac{\sqrt{\log n}}{\sqrt{\pi} n^{1-\alpha}} + \frac{1}{\pi\alpha} + \frac{1}{\pi\alpha} \int G(\theta)(1 - G(\theta)) d\theta,
\]

\[
(\log n) E_G\|\hat{G}_n - G\|^2 \leq \frac{\log n}{\sqrt{\pi} n^{1-\alpha}} + \frac{C_i^2\|G^*(t)\|^2}{2\pi\alpha} + \frac{\log n}{\pi\alpha} \int G(\theta)(1 - G(\theta)) d\theta,
\]

and if \( \int \log^2(1 + |x|) dG(x) < \infty \) and (28) holds, then

\[
\limsup_{n \to \infty} (\log n) E_G|\hat{G}_n(a) - G(a)|^2 \leq \frac{M_3^2 C_1^2}{\alpha}.
\]

**Example 2** (Cauchy, continuation). Since \( E[X] = \infty \), Theorem 3 is not applicable. If \( \int \log^2(1 + |x|) dG(x) < \infty \) and (28) holds, then by Theorem 4

\[
\limsup_{n \to \infty} (\log n)^2 E_G|\hat{G}_n(a) - G(a)|^2 \leq M_3^2 C_i^2 / \alpha^2.
\]

**Example 3** (Double exponential, continuation). Let \( c_n = \alpha n^{1/5} \). We have

\[
\int F_0(x)(1 - F_0(x)) dt = 3/4. \text{ If } \int G(\theta)(1 - G(\theta)) d\theta < \infty \text{, then by Theorem 3}
\]

\[
\limsup_{n \to \infty} n^{1/5} E_G\|\hat{G}_n - G\|^2 \leq 3\alpha^4/4 + (1 + C_i^2)/(\pi\alpha).
\]

Let \( c_n = \alpha n^{1/6} \). If \( \int G(\theta)(1 - G(\theta)) d\theta < \infty \), then by Theorem 3

\[
\limsup_{n \to \infty} n^{1/3} E_G\|\hat{G}_n - G\|^2 \leq 3\alpha^4/4 + C_i^2\|G^*(t)\|^2/(2\pi\alpha^2).
\]

Let \( c_n = \alpha(n/\log^2 n)^{1/6} \). If \( \int \log^2(1 + |x|) dG(x) < \infty \) and (28) holds, then by Theorem 4

\[
\limsup_{n \to \infty} n^{1/3}(\log n)^{-2/3} E_G|\hat{G}_n(a) - G(a)|^2 \leq 16\alpha^4/\pi^2 + M_3^2 C_i^2 / \alpha^2.
\]

Both Theorems 3 and 4 require moment conditions on \( F_0 \) as well as \( G \). However, these moment conditions are not necessary if we estimate

\[
G(a, b) = G(b) - G(a) = \frac{G(b^+) + G(b^-)}{2} - \frac{G(a^+) + G(a^-)}{2}.
\]
Define
\begin{equation}
I_n(x, a, b) = \int_a^b K_n(x, \theta) d\theta = \frac{1}{2\pi} \int_{\mathbb{R}} \left( e^{ix\theta} \frac{e^{-ita} - e^{-itb}}{itf^*_0(t)} \right) dt,
\end{equation}
\begin{equation}
\hat{G}_n(a, b) = \min \left( \sum_{j=1}^n I_n(X_j, a, b)/n \right),
\end{equation}
\begin{equation}
\mathcal{I}_3 = \mathcal{I}_3(a, b, \delta, M_3) = \mathcal{I}_3(a, \delta, M_3) \cap \mathcal{I}_3(b, \delta, M_3),
\end{equation}
where \( \mathcal{I}_3(a, \delta, M_3) = \{ G : (28) \text{ holds for } G \} \).

**Theorem 5.** Let the estimator \( \hat{G}_n(a, b) \) be given by (31). Choose the constants \( c_n \) such that
\begin{equation}
\frac{1}{n} \leq \frac{c_0}{c_n} \left| f^*_0(c_n) \right|^2,
\end{equation}
\begin{equation}
\min_{|t| \leq 2/|b-a|} \frac{2}{b-a} \left| f^*_0(t) \right| \geq c_n \left| f^*_0(c_n) \right|,
\end{equation}
\begin{equation}
\min_{2/|b-a| \leq |t| \leq c_n} |tf^*_0(t)| = c_n \left| f^*_0(c_n) \right|.
\end{equation}

(i) For any \( a \leq b \), \( \lim_{n \to \infty} E[\hat{G}_n(a, b) - G(a, b)]^2 = 0 \).
(ii) Let \( \epsilon_0(x) = \int_{-\infty}^{\infty} yk(y) dy \). Then
\begin{equation}
\sup_{G \in \mathcal{I}_3(a, b, \delta, M_3)} c_0^2 E_G \left| \hat{G}_n(a, b) - G(a, b) \right|^2 \leq \frac{2c_0}{\pi^2} \int |f^*_0(t)| dt + 4 \left[ \epsilon_0(c_n \delta)/\delta + M_3C_1 \right]^2.
\end{equation}
(iii) Suppose that \( \lim_{n \to \infty} E|\hat{G}_n(X, a, b)| = \infty \),
\begin{equation}
\lim_{n \to \infty} \sup_x |I_n(x, a, b)|/\sqrt{nEI_n^2(X, a, b)} = 0,
\end{equation}
\begin{equation}
\liminf_{n \to \infty} c_n^2 EI_n^2(X, a, b)/n > 0.
\end{equation}

Let \( \hat{\sigma}_n^2 = \hat{\sigma}_n^2(a, b) = \Sigma_{j=1}^n I_n^2(X_j, a, b)/n \). If \( g(a) = G'(a) \) and \( g(b) = G'(b) \) exist, then
\begin{equation}
\sqrt{n} \left( \hat{G}_n(a, b) - G(b) + G(a) \right)/\hat{\sigma}_n \to_{\mathcal{D}} N(0, 1) \quad \text{if } G(b) - G(a) \in (0, 1),
\end{equation}
\begin{equation}
\sqrt{n} \left( \hat{G}_n(a, b) - G(a) \right)/\hat{\sigma}_n \to_{\mathcal{D}} \left[ N(0, 1)^+ \right] \quad \text{if } G(b) = G(a),
\end{equation}
\begin{equation}
\sqrt{n} \left( \hat{G}_n(a, b) - 1 \right)/\hat{\sigma}_n \to_{\mathcal{D}} \left[ N(0, 1)^+ \right] \quad \text{if } G(b) - G(a) = 1.
\end{equation}
(iv) Suppose that \( g'(a) = G''(a) \) and \( g'(b) = G''(b) \) exist. If \( \lim_{n \to \infty} c_n^2/n |f^*_0(c_n)|^2 = 0 \), then
\begin{equation}
\lim_{n \to \infty} c_n^2 \left( \hat{G}_n(a, b) - G(b) + G(a) \right) = \left[ g'(b) - g'(a) \right] \int x^2k(x) dx/2, \quad \text{in mean square}.
\end{equation}
PROOF. By (33) for $|t| \leq c_n$,
\[
\max_{|t| \leq c_n} \left| \frac{e^{-ita} - e^{-itb}}{tf_0^\ast(t)} \right| \leq \min \left( \frac{|b - a|}{|f_0^\ast(t)|}, \frac{2}{|tf_0^\ast(t)|} \right) \leq \frac{2}{c_n|f_0^\ast(c_n)|}.
\]

The argument of (16) provides a bound for the variance term. For the bias term we have
\[
\left| EI_n(X, a, b) - G(a, b) \right| = \left| \int \left( [G(b + x/c_n) - G(b)] - [G(a + x/c_n) - G(a)] \right) k(x) \, dx \right|
\leq 2M_3 \int |x| k(x) \, dx + 2 \int_\delta^{c_n} k(x) \, dx,
\]
by (8) and the Lipschitz condition. The rest of the proof is similar to that of Theorem 2 and omitted. □

**Example 1** (Normal, continuation). The estimator $\hat{G}_n(a, b)$ is given by (31) with
\[
I_n(x, a, b) = \pi^{-1} \int t^{-1} \sin(t(b - a)/2) \cos(t(x - (b + a)/2)) \cdot k^\ast(t/c_n) e^{t^2/2} \, dt.
\]
It follows from part (ii) of Theorem 5 that
\[
\sup_{G \in \mathcal{G}(a, b, \delta, M_3)} (\log n) E_G |\hat{G}_n(a, b) - G(a, b)|^2 \leq \frac{\sqrt{8} \log n}{\sqrt{\pi^3} a n^{-1 - \alpha}} + \frac{4}{\alpha} \left[ \varepsilon(\delta \sqrt{\alpha \log n})/\delta + M_3 C_1 \right]^2.
\]
Since the standard deviation is of smaller order than the bias, we do not apply part (iii). If $g'(a)$ and $g'(b)$ exist, then by part (iv)
\[
\lim_{n \to \infty} (\log n) (\hat{G}_n(a, b) - G(b) + G(a)) = [g'(b) - g'(a)] C_2/(2\alpha), \quad \text{in mean square}.
\]

**Example 2** (Cauchy, continuation). Similar to the normal case, we have
\[
\sup_{G \in \mathcal{G}(a, b, \delta, M_3)} (\log n)^2 E_G |\hat{G}_n(a, b) - G(a, b)|^2 \leq \frac{4 \log n}{\pi^3 a n^{-1 - \alpha}} + \frac{4}{\alpha^2} \left[ \varepsilon(\delta \alpha \log n)/\delta + M_3 C_1 \right]^2.
\]
and if \( g'(a) \) and \( g'(b) \) exist, then

\[
\lim_{n \to \infty} (\log n) (\hat{G}_n(a, b) - G(b) + G(a)) \leq [g'(b) - g'(a)] C_2 / (2\alpha^2), \quad \text{in mean square.}
\]

**Example 3** (Double exponential, continuation). Let \( c_n = \alpha n^{1/5}, \alpha > 0 \). Then

\[
\lim_{n \to \infty} \sup_{G \in \mathcal{G}(a, b, \delta, M_3)} n^{2/5} E[G] \left| \hat{G}_n(a, b) - G(a, b) \right|^2 \leq 2\alpha^3 / \pi + 4M_3^2C_1^2 / \alpha^2.
\]

Let \( \sigma_n^2 = \sum_{j=1}^n I_n^2(X_j, a, b) / n \). If \( g(a) \) and \( g(b) \) exist, then by Lemma 1 in the Appendix

\[
\sqrt{n} \left( \hat{G}_n(a, b) - G(b) + G(a) \right) / \sigma_n \to_d N(0, 1) \quad \text{if} \ G(b) - G(a) \in (0, 1),
\]

\[
\sqrt{n} \hat{G}_n(a, b) / \sigma_n \to_d \left[ N(0, 1) \right]^+ \quad \text{if} \ G(b) = G(a),
\]

\[
\sqrt{n} \left( \hat{G}_n(a, b) - 1 \right) / \sigma_n \to_d - \left[ N(0, 1) \right]^+ \quad \text{if} \ G(b) - G(a) = 1.
\]

**4. Lower bounds for the optimal rate of convergence.** We study lower bounds for the optimal rate of convergence in this section. Our basic idea is borrowed from Le Cam (1972) and Hájek (1972) among other papers on asymptotic information and efficiency. Instead of directly using the LAN condition, we observe that a lower bound for the rate of convergence can be obtained for any pair of contiguous sequences in infinitesimal neighborhoods of \( f(x; G) \). As demonstrated by Example 1 in Section 1, Fourier methods can be used to derive contiguous sequences. We consider estimating mixing densities and distributions in two separate sections.

**4.1. Lower bounds for estimating mixing densities.** We shall try to find density functions \( \hat{g}_j = G_j, j = 1, 2 \), such that \( f(\cdot; G_1) \) and \( f(\cdot; G_2) \) are relatively close but not \( G_1 \) and \( G_2 \) for a given sample size \( n \). Let \( g_0 = G_0 \) be a density function and \( G \) be a distribution function. For constants \( b_n, d_n > 0 \) and \( e_n \) define

\[
(35) \quad dG_1(\theta) = (1 - w) dG(\theta) + w g_0(\theta) d\theta, \quad 0 < w < 1,
\]

\[
(36) \quad dG_2(\theta) = dG_1(\theta) + \left[ w / (4d_n) \right] \left[ \cos(d_n \theta - b_n) - e_n \right] g_0(\theta) d\theta.
\]

It follows from the Riemann–Lebesgue lemma that \( \lim_{d_n \to \infty} d_n \left[ f(x; G_2) - f(x; G_1) \right] = 0 \), so that \( f(\cdot; G_1) \) and \( f(\cdot; G_2) \) are at least as close as \( o(d_n^{-1}) \) and \( |G_1 - G_2| \) is bounded from below by some thing of order \( d_n^{-1} \) for large \( d_n \). Note that we have contiguous sequences if the \( o(d_n^{-1}) \) is actually \( O(n^{-1/2}) \).

**Theorem 6.** Suppose there exist a density function \( g_0 = G_0 \) and nonnegative functions \( \rho(t) \) and \( u(x) \) such that \( \rho(t)/t \downarrow 0 \) as \( t \to \infty \) and

\[
(37) \quad \left| \int e^{it\theta} f(x|\theta) g_0(\theta) \, d\theta \right| \leq \rho(t) u(x) f(x; G_0), \quad \forall \ t \geq 1, \ \rho(1) = 1.
\]
Let \( G \) be a distribution function with derivative \( g(a) \) at \( \theta = a \). Let \( G_1 \) and \( G_2 \) be defined by (35) and (36) with

\[
e_n = \int \cos(d_n \theta - b_n) g_0(\theta) \, d\theta \in (-1, 1), \quad \rho(d_n)/d_n \leq n^{-1/2}.
\]

(38) Then for any estimator \( \tilde{g}_n(a) \) based on \( X_1, \ldots, X_n \),

\[
\max_{j=1,2} P_j \left[ d_n \tilde{g}_n(a) - g_j(a) \right] \geq \frac{w}{8} \left| \cos(d_n a - b_n) - e_n \right| g_0(a) \left[ 2(1 + e^{2M}) \right]^{-1},
\]

where \( P_j = P_{G_j}, \ E_j = E_{G_j}, \ g_j = G_j', \ j = 0, 1, 2, \) and \( M = 1 + 3E(u(X) + E_0u(X))^2)/16 \). Furthermore, if \( G \) has a density \( g \) and \( M < \infty \), then

\[
\inf \max_{n \geq 1, j=1,2} d_n \int E_j | \tilde{g}_n(\theta) - g_j(\theta) |^2 \, d\theta > 0.
\]

(40)

**Remarks.** By the Riemann–Lebesgue lemma \( \lim e_n = 0 \). If \( g_0(a) > 0 \) and \( b_n = d_n a \), then \( (w/8)\cos(d_n a - b_n) - e_n \) is bounded away from 0. (2) If \( G_0 \in \mathcal{S}_j \), then such pairs \( (G_1, G_2) \) are dense in \( \mathcal{S}_j \), \( j = 1, 2 \), where \( \mathcal{S}_1 \) and \( \mathcal{S}_2 \) are defined by (8) and (13), respectively. (3) The constant \( M \) does not depend on \( n, d_n, b_n \) or \( e_n \).

For the location case the integration on the left-hand side of (37) is the convolution of \( f_0(x) \) and \( e^{ix}g_0(x) \) for fixed \( t \). Since \( e^{ix}g_0(x) \) has the Fourier transformation \( g_0^*(t + s) \), we have

\[
\int e^{ixt}f(x|\theta) g_0(\theta) \, d\theta = (2\pi)^{-1} \int e^{-ixs}f_0^*(s) g_0^*(t + s) \, ds,
\]

so that \( \rho(t) \) is basically a mixture of the tail of \( f_0^* \) near \( t \) if \( g_0^* \) has very thin tails. The examples below suggest that \( \rho(t) \) and \( |f_0^*(t)| \) have similar behavior for large \( t \). For smooth \( f_0 \), we have \( f_0^* \) with thin tails and slow lower bounds for the optimal rate of convergence.

**Corollary 1.** Suppose that the conditions of Theorem 6 hold with \( E_G u^2(X) < \infty \) and \( G_0 \in \mathcal{S}_1(M_0) \) for some \( M_0 < \infty \), where \( \mathcal{S}_1 \) is defined by (8). Then for any estimator \( \tilde{g}_n \) and \( M_1 > 0 \),

\[
\inf \sup_{n \geq 1} d_n \int E_G(\tilde{g}_n(\theta) - g(\theta))^2 \, d\theta > 0.
\]

**Proof.** Let \( G_j, j = 1, 2 \), be defined by (35) and (36) with \( G \in \mathcal{S}_1(M_1/2) \) and \( E_G u^2(X) < \infty \). Since

\[
\|tg_0^*(t)\| \leq \|tg_0^*(t)\| + (w/(8d_n))(2\|tg_0^*(t + d_n)\| + 2e_n\|tg_0^*(t)\|)
\]

\[
= \|tg_0^*(t)\| + (w/4)(\|t + d_n\| g_0^*(t)/d_n + \|tg_0^*(t)\|/d_n),
\]
there exists a (small) \( w > 0 \) such that \( \| t g_j^w (t) \| < M_j \) for all \( j = 1, 2 \) and \( n \geq 1 \). The corollary follows from (40) and the fact that \( M < \infty \). \( \square \)

**Corollary 2.** Suppose that the conditions of Theorem 6 hold with \( E_{G_0} u^2 (X) < \infty \) and \( G_0 \in \mathscr{G}_2 (a, \delta_0, M_2) \) for some \( \delta_0 > 0 \) and \( M_2 < \infty \), where \( \mathscr{G}_2 \) is defined by (13). Then for any estimator \( \tilde{g}_n \) and constants \( \delta < \infty \) and \( M > 0 \) there exists an \( \varepsilon > 0 \) such that

\[
\inf_{n \geq 1} \sup_{G \in \mathscr{G}_2 (a, \delta, M)} P_G \{ d_n | \tilde{g}_n (a) - g(a) | > \varepsilon \} > 0.
\]

**Example 1** (Normal, continuation). The condition (37) holds with

\[ G_0 \sim N (0, \sigma^2), \quad \rho (t) = \exp \left[ - (t^2 - 1) \sigma^2 / (2(1 + \sigma^2)) \right] \]

and

\[ u (x) = e^{\sigma^2 (2x + 1)} \]

so that \( d_n = \sqrt{1 + (1 + \sigma^{-2}) \log n} \), which implies by Corollaries 1 and 2 that there exists an \( \varepsilon > 0 \) such that for any statistics \( \tilde{g}_n \) or \( \tilde{g}_n (\cdot) \),

\[
\inf_{n \geq 1} \sup_{G \in \mathcal{G}_1 (M_1)} \log n E_{G_0} \| \tilde{g}_n - g \|^2 > \varepsilon,
\]

\[
\inf_{n \geq 1} \sup_{G \in \mathcal{G}_2 (a, \delta, M_2)} P_G \{ \sqrt{\log n} | \tilde{g}_n - g(a) | > \varepsilon \} > \varepsilon.
\]

Hence, our estimators achieve the optimal rate of convergence \( (\log n)^{-1/2} \) for the classes \( \mathcal{G}_1 \) and \( \mathcal{G}_2 \).

**Example 2** (Cauchy, continuation). Let \( g_0 (\theta) = 1 / (\pi (\sigma^2 + \theta^2)) \). Then by the Cauchy residue theorem for \( t \geq 0 \),

\[
\int e^{it \theta} f (x | \theta) g_0 (\theta) \, d \theta
\]

\[
= (\sigma / \pi)^2 \int e^{it \theta} (1 + (x - \theta)^2)^{-1} (\sigma^2 + \theta^2)^{-1} \, d \theta
\]

\[
= \sigma e^{i \theta x} (\sigma^2 + x^2 - 1 - 2xi) + e^{-\sigma t} (x^2 + 1 - \sigma^2 + 2\sigma x i)
\]

\[
\pi [(\sigma + 1)^2 + x^2] [(\sigma - 1)^2 + x^2]
\]

\[
= \exp \left[ - \min (1, \sigma) t \right] \frac{(\sigma + 1) / \pi}{(\sigma + 1)^2 + x^2} h (x, t, \sigma), \quad \text{say}.
\]

By algebra \( \sup | h (x, t, \sigma) | : - \infty < x < \infty, \ t \geq 0 \} = M(\sigma) < \infty \), so that

\[
\left| \int e^{it \theta} f (x | \theta) g_0 (\theta) \, d \theta \right| \leq \exp \left[ - \min (1, \sigma) | t | \right] f (x; G_0) M(\sigma), \quad \forall \ t,
\]

which implies that (37) holds with \( \rho (t) = \exp \left[ - \min (1, \sigma) | t | - 1 \right] \) and \( u (x) = \)
$e^{-\min(1,\sigma)}M(\sigma)$. It follows that $d_n = 1 + (\log n)/[2 \min(1, \sigma)]$. By Corollaries 1 and 2 for some $\varepsilon > 0$,

$$\inf_{n \geq 1} \sup_{G \in \mathcal{G}_1} (\log n) \|\tilde{g}_n - g\|^2 > \varepsilon, \inf_{n \geq 1} \sup_{G \in \mathcal{G}_2} P_G\{|\tilde{g}_n - g(a)| > \varepsilon\} > \varepsilon.$$  

Hence, our estimators achieve the optimal rate of convergence $(\log n)^{-1}$ for the classes $\mathcal{G}_1$ and $\mathcal{G}_2$.

**Example 3** (Double exponential, continuation). To derive lower bounds for the optimal rate of convergence, we set $g_0(\theta) = e^{-|\theta|}/2$. Since

$$\int e^{it\theta} e^{-|x-\theta|} d\theta = e^{-x}\left(\frac{4}{4 + it^2} + \frac{2(e^{it} - 1)}{t^2 + 2it}\right), \quad \forall x \geq 0,$$

$$\left|\int e^{it\theta} f(x|\theta) g_0(\theta) d\theta / f(x; G_0) \right| = \frac{1}{1 + |x|} \left|\frac{4}{4 + t^2} + \frac{2(e^{it} - 1)}{t^2 + 2it}\right| \leq 8/t^2, \quad \forall x \geq 0,$$

so that $\rho(t) = t^{-2}$ and $u(x) = 3$. Since $\|g_0^*\|^2 = 1/2$, by Corollaries 1 and 2 for some $\varepsilon > 0$,

$$\inf_{n \geq 1} \sup_{G \in \mathcal{G}_1} n^{1/3} E_G \|\tilde{g}_n - g\|^2 > \varepsilon, \quad \inf_{n \geq 1} \sup_{G \in \mathcal{G}_2} P_G\{|n^{1/3} \tilde{g}_n - g(a)| > \varepsilon\} > \varepsilon.$$  

**4.2. Lower bounds for estimating mixing distributions.** Now it is easy to study the case of estimating mixing distributions. Let $g_0 = G_0^*$ be a density function and $G$ be an arbitrary distribution function. Define $dG_1(\theta)$ by (35) and

$$dG_2(\theta) = dG_1(\theta) + (w/4)(\cos(d_n\theta - b_n) - e_n)g_0(\theta) d\theta.$$

**Theorem 7.** Suppose (37) holds such that $\rho(t) \downarrow 0$ as $t \to \infty$. Define $G_1$ and $G_2$ by (35) and (41) with constants $e_n$ in (38) and $\rho(d_n) \leq n^{-1/2}$. Then for any Borel function $h$ and estimator $\tilde{G}_n(h)$ for $G(h) = \int h(\theta)dG(\theta)$ based on $X_1, \ldots, X_n$,

$$\max_{j=1,2} P_j\left(\left|\tilde{G}_n(h) - G_j(h)\right| \geq \frac{w}{8} \int h(\theta)(\cos(d_n\theta - b_n) - e_n)g_0(\theta) d\theta \right) \geq \left[2(1 + e^{2M})\right]^{-1},$$

where $P_j$, $j = 1, 2$, and $M$ are as in Theorem 6.

We omit the proof since it is almost identical to that of Theorem 6. Define

$$\mathcal{G}_3' = \mathcal{G}_3(a, b, \delta, M_3)$$

$$= \mathcal{G}_3(a, b, \delta, M_3) \cap \{G: G(a+) = G(a-), G(b+) = G(b-)\}.$$
COROLLARY 3. Suppose that the conditions of Theorem 7 hold with a differentiable density function \( g_0 = G_0 \) such that \( E_{G_0} u^2(X) < \infty, \int |g_0'(\theta)| d\theta < \infty \) and \( g_0(a) + g_0(b) > 0 \). Let \( d_n \) be such that \( \rho(d_n) = 1/\sqrt{n} \). Then for any \( \delta \geq 0 \) and \( M_3 > 0 \) there exists an \( \varepsilon > 0 \) such that for any estimator \( \hat{G}_n(a, b, \delta, M_3) \),

\[
\inf_{n \geq 1} \sup_{G \in \mathcal{F}_3(a, b, \delta, M_3)} P_G \left\{ d_n \left| \hat{G}_n(a, b) - (G(b) - G(a)) \right| \geq \varepsilon \right\} > 0.
\]

PROOF. Let the constants \( d'_n, b'_n \) and \( e'_n \) be such that \( d'_n |b - a|/2 = 2k_n \pi + \pi/2 \) for some integer \( k_n \), \( d_n \leq d'_n < d_n + 4\pi/|b - a| \), \( b'_n = d'_n(b + a)/2 \) and \( e'_n = \int \cos(d'_n \theta - b'_n) g_0(\theta) d\theta \). Then \( \rho(d'_n) \leq 1/\sqrt{n} \) and by Theorem 7

\[
\sup_{G \in \mathcal{F}_3(a, b, \delta, M_3)} P_G \left\{ d_n \left| \hat{G}_n(a, b) - (G(b) - G(a)) \right| \geq \frac{w}{8} \int_a^b (\cos(d'_n \theta - b'_n) - e'_n) g_0(\theta) d\theta \right\}
\]

\[
\geq \frac{1}{2(1 + e^{2M})} \frac{1}{d_n}^{1/2},
\]

which implies the corollary, provided that

\[
\liminf \left| d'_n \int_a^b (\cos(d'_n \theta - b'_n) - e'_n) g_0(\theta) d\theta \right| > 0,
\]

since \( d_n/d'_n \to 1 \). Integrating by parts, we have by the Riemann–Lebesgue lemma

\[
d'_n \int_a^b (\cos(d'_n \theta - b'_n) - e'_n) g_0(\theta) d\theta
\]

\[
= g_0(\theta) \sin(d'_n \theta - b'_n) \bigg|_a^b - \int_a^b \sin(d'_n \theta - b'_n) g_0'(\theta) d\theta
\]

\[
+ \int_a^b g_0(\theta) d\theta \int \sin(d'_n \theta - b'_n) g_0'(\theta) d\theta
\]

\[
= g_0(b) \sin(2k_n \pi + \pi/2) - g_0(a) \sin(-2k_n \pi - \pi/2) + o(1)
\]

\[
= g_0(a) + g_0(b) + o(1).
\]

EXAMPLE 1 (Normal, continuation). Similar to the case of estimating mixing density

\[
\inf_{n \geq 1} \sup_{G \in \mathcal{F}_3(a, b, \delta, M_3)} P_G \left\{ \sqrt{n} \left| \hat{G}_n - (G(b) - G(a)) \right| > \varepsilon \right\} > \varepsilon, \ 	ext{for some } \varepsilon > 0.
\]

Again, our estimators achieve the optimal rate of convergence \( (\log n)^{-1/2} \) for the class \( \mathcal{F}_3 \).
Example 2 (Cauchy, continuation). Similar to the case of estimating mixing density

\[
\inf_{n \geq 1} \sup_{G \in \mathcal{G}(a, b, \delta, M_3)} P_G\{ (\log n) | \hat{G}_n - (G(b) - G(a)) | > \varepsilon \} > \varepsilon, \quad \text{for some } \varepsilon > 0.
\]

Our estimators also achieve the optimal rate of convergence \((\log n)^{-1}\) for the class \(\mathcal{G}_3\).

Example 3 (Double exponential, continuation). For this case we have

\[
\inf_{n \geq 1} \sup_{G \in \mathcal{G}(a, b, \delta, M_3)} P_G\{ n^{1/4} | \hat{G}_n - (G(b) - G(a)) | > \varepsilon \} > \varepsilon, \quad \text{for some } \varepsilon > 0.
\]

Appendix

Proof of Theorem 3. Since \( \int |x| f_n(x) \, dx < \infty \), \( J_n(x, a) \) is well defined and \( K_n(x, \cdot) \) is Riemann integrable. Since the Fourier transformation of \( H - G \) is \( (G^* - H^*)/(it) \), by (22) and the Plancherel identity

\[
(2\pi) E\| \hat{G}_n - G \|^2 \leq \int E \left| \frac{k^* (t/c_n) F_n^*(t) - f_0^*(t) G^*(t)}{it f_0^*(t)} \right|^2 dt.
\]

Let \( \theta_1 \sim G \) and \( X_1|\theta_1 \sim f(\cdot|\theta_1) \). Since \( E[e^{itX_1}|\theta_1] = f_0^*(t)e^{it\theta_1} \), we have

\[
\text{Var}(e^{itX_1}) = E|e^{itX_1} - f_0^*(t)e^{it\theta_1}|^2 + \text{Var}(f_0^*(t)e^{it\theta_1}) = E|e^{it(X_1 - \theta_1)} - F_0^*(t)|^2 + |f_0^*(t)|^2 \text{Var}(e^{it\theta_1} - G^*(t))^2.
\]

It follows from the Plancherel identity that

\[
(2\pi)^{-1} \int E|e^{it\theta_1} - G^*(t)|^2 t^{-2} \, dt = E\int |G_1(\theta) - G(\theta)|^2 \, d\theta = \int G(\theta)(1 - G(\theta)) \, d\theta,
\]

\[
(2\pi)^{-1} \int E|e^{it(X_1 - \theta_1)} - F_0^*(t)|^2 t^{-2} \, dt = \int F_0(x)(1 - F_0(x)) \, dx,
\]

so that \( E\| \hat{G}_n - G \|^2 \) is bounded by

\[
\int \frac{|k^*(t/c_n)|^2 \text{Var}(F_n^*(t))}{2\pi |tf_0^*(t)|^2} \, dt + \int \frac{|k^*(t/c_n) EF_n^*(t) - f_0^*(t) G^*(t)|^2}{2\pi |tf_0^*(t)|^2} \, dt \leq \int \frac{|k^*(t/c_n)|^2 \text{Var}(e^{itX_1})}{2\pi n |tf_0^*(t)|^2} \, dt + \int \frac{|(k^*(t/c_n) - 1)f_0^*(t) G^*(t)|^2}{2\pi |tf_0^*(t)|^2} \, dt \leq \frac{\int F_0(x)(1 - F_0(x)) \, dx}{n |f_0^*(c_n)|^2} + \int G(\theta)(1 - G(\theta)) \, d\theta / n + \int \frac{|G^*(t)(k^*(t/c_n) - 1)|^2}{2\pi t^2} \, dt.
\]
Hence, (23) and (24) follow from
\[
\int |G^*(t)(k^*(t/c_n) - 1)/t|^2 \, dt \leq \int_{-c_n}^{c_n} + 2 \int_{c_n}^{\infty} \leq \frac{2}{c_n} \left[ \left( \int |x| k(x) \, dx \right)^2 + 1 \right],
\]
\[
\int |G^*(t)(k^*(t/c_n) - 1)/t|^2 \, dt \leq c_n^{-2} \left( \int |x| k(x) \, dx \right)^2 \|G^*(t)\|^2.
\]
\[\square\]

**Proof of Theorem 4.** By (21)
\[
(2\pi)^2 \text{Var}(J_n(X, a)) \leq E \left| \int e^{-i\alpha t} k^*(t/c_n) [e^{i\alpha X} - 1]/(t f^*_0(t)) \, dt \right|^2 \leq \left| f^*_0(c_n) \right|^{-2} E \left( 2 \int_{0}^{c_n} |e^{i\alpha X} - 1|/t \, dt \right)^2.
\]

Since \(|e^{i2\pi t} - 1|^2 = 2(1 - \cos(2\pi t)) = 4 \sin^2(\pi t)\) and
\[
\int_{0}^{\pi} |\sin(\pi t)/t| \, dt \leq \int_{0}^{1} |\sin(\pi t)/t| \, dt + \sum_{1 \leq k < x} k^{-1} \int_{0}^{1} |\sin(\pi t)\, dt \leq \int_{0}^{1} (\pi t - (\pi t)^3/3! + (\pi t)^5/5!)/t \, dt + (2/\pi)(1 + \log^+ x)
\]
\[
\leq \pi + (2/\pi)\log^+ x,
\]
\[
\int_{0}^{c} |(e^{i\alpha x} - 1)/x| \, dt = 2 \int_{0}^{cx/2\pi} |\sin(\pi s)/s| \, ds \leq 2\pi + (4/\pi)\log^+ (cx/2\pi),
\]
\[\forall x \geq 0.
\]
It follows that
\[
(2\pi)^2 \text{Var}(J_n(X, a)) \leq \left| f^*_0(c_n) \right|^{-2} E \left( 4\pi + (8/\pi)\log^+ (c_n|X|/(2\pi)) \right)^2
\]
\[
\leq \left| f^*_0(c_n) \right|^{-2} (8/\pi + o(1))^2 (\log^+ c_n)^2.
\]

Hence, by (26)
\[
c_n^2 E_G |\hat{G}_n(a) - G(a)|^2
\]
\[
\leq c_n^2 \text{Var}(J_n(X, a))/n + c_n^2 |EJ_n(X, a) - G(a)|^2
\]
\[
\leq (2\pi)^{-2} c_n^2 \left| f^*_0(c_n) \right|^{-2} (8/\pi + o(1))^2 (\log^+ c_n)^2 /n
\]
\[
+ \left| c_n \int G(\theta)c_n k(c_n(a - \theta)) \, d\theta - G(a) \right|^2
\]
\[
\leq c_0(4/\pi)^2 + o(1)
\]
\[
+ \left| \int_{0}^{\infty} c_n [G(a + x/c_n) + G(a - x/c_n) - 2G(a)] k(x) \, dx \right|^2
\]
\[
\leq c_0(4/\pi)^2 + o(1) + \left( \int M_3|k(x) \, dx \right)^2.
\]
\[\square\]
PROOF OF THEOREM 6. We shall first prove (39) under the additional assumption that \( E_1|\Lambda_n| \leq M \), where \( \Lambda_n = \sum_{j=1}^n \log(f(X_j; G_2)/f(X_j; G_1)) \) is the log-likelihood ratio. By symmetry we may assume \( g_2(a) \geq g_1(a) \). Let \( p \) be the left-hand side of (39) and \( R \) be the event that \( \tilde{g}_n(a) > [g_1(a) + g_2(a)]/2 \). Since \( d_n[g_2(a) - g_1(a)] = (w/4)(cos(d_n \theta - b_n) - e_n)g_0(a) \), it follows from the definition of \( p \) that \( P_1(R) \leq p \) and \( P_2(R^c) \leq p \). Therefore,

\[
1/2 \leq P_1(|\Lambda_n| \leq 2M) \leq P_1(R) + P_1(R^c, |\Lambda_n| \leq 2M) \leq p + E_1e^{\Lambda_n+2M}I(R^c) = p + P_2(R^c)e^{2M} \leq p(1 + e^{2M}).
\]

Let us prove that \( E_1|\Lambda_n| \leq M \). Set \( v(x) = f(x; G_2)/f(x; G_1) - 1 \). Since \( d_n \geq 1 \) by (38), it follows from (35) and (36) that \(|v(x)| \leq w_{f(x, G_0)}/(2f(x; G_1)) \leq 1/2 \), which implies that

\[
\sum_{j=1}^n v(X_j) - 2 \sum_{j=1}^n v(X_j) \leq \Lambda_n = \sum_{j=1}^n \log(1 + v(X_j)) \leq \sum_{j=1}^n v(X_j).
\]

Since \( f(x; G_2)/f(x; G_1) \) is a likelihood ratio, \( E_1v(X) = 0 \), so that

\[
E_1|\Lambda_n| \leq E_1 \sum_{j=1}^n v(X_j) + 2E_1 \sum_{j=1}^n v^2(X_j)
\]

\[
\leq 2nE_1v^2(X) + \sqrt{nE_1v^2(X)}.
\]

It follows from (38) and (37) that

\[
|e_n| = \left| \int f(x|\theta)\mu(dx)\cos(d_n \theta - b_n)g_0(\theta) \right| d\theta
\]

\[
\leq \left| \int f(x|\theta)\mu(dx)e^{i(d_n \theta - b_n)}g_0(\theta) \right| d\theta
\]

\[
\leq \left| \rho(d_n)u(x)f(x; G_0)\mu(dx) = \rho(d_n)E_0u(X) \right|
\]

and that

\[
|v(x)| = |f(x; G_2)/f(x; G_1) - 1|
\]

\[
\leq \left[ w/(4d_n) \right] \left[ \rho(d_n)u(x)f(x; G_0) + |e_n|f(x; G_0)/f(x; G_1) \right] \leq \left[ \rho(d_n)u(x) + |e_n| \right]/(4d_n) \leq n^{-1/2}[u(x) + E_0u(X)]/4.
\]

Hence, \( E_1|\Lambda_n| \leq M \) by (43) and (44).

Let us prove (40). It follows from (39) that

\[
2 \max_{j=1,2} d_n^2 E_1\|\tilde{g}_n - g_j\|^2
\]

\[
\geq d_n^2 \left( E_1\|\tilde{g}_n - g_1\|^2 + E_2\|\tilde{g}_n - g_2\|^2 \right)
\]

\[
\geq \left[ 2(1 + e^{2M}) \right]^{-1} \int (w/8)^2 |cos(d_n \theta - b_n) - e_n|^2 g_0^2(\theta) \right| d\theta.
\]
Let \( h(\theta) = \min(g_0^2(\theta), C) \) for some \( C > 0 \). Then \( \int h < \infty \). It follows from (38) and the Riemann–Lebesgue lemma that

\[
\liminf \int |\cos(d_n \theta - b_n) - e_n^2 g_0^2(\theta)| d\theta \\
\geq \lim \int \cos^2(d_n \theta - b_n) h(\theta) d\theta \\
= \lim \int (1 + \cos(2d_n \theta - 2b_n)) h(\theta) d\theta / 2 = \int h(\theta) d\theta / 2 > 0.
\]

The proof is complete since \( \int |\cos(d_n \theta - b_n) - e_n|^2 g_0^2(\theta) d\theta > 0, \forall n. \Box \)

We use the following lemma to check the conditions (15) and (34) for Example 3.

**Lemma 1.** Suppose \( f_0(x) = e^{-|x|}/2 \). Let \( K_n(x, a) \) and \( I_n(x, a) \) be given by (19) and (30). Then

\[
\lim_{n \to \infty} c_n^{-3} E_G^k |K_n(x, a)|^2 = (2\pi)^{-1} f(a; G) \| t^2 k^*(t) \|^2,
\]

\[
\lim_{n \to \infty} c_n^{-3} E_G^k |I_n(x, a)|^2 = (2\pi)^{-1} (f(a; G) + f(b; G)) \| t k^*(t) \|^2.
\]

**Proof.** We shall first prove the lemma based on the fact that for any real-valued function \( h(x) \) satisfying \( \int x^2 |h(x)| dx < \infty \) and \( h^*(t) = 0, \forall |t| > 1, \)

\[
\lim_{C \to \infty} (2\pi)^{-1} \int e^{-i(t-s)a} f^*(t-s) h^*(t/c) h^*(s/c) dt ds
\]

\[
= f(a) \| h^*(t) \|^2,
\]

\[
\lim_{c \to \infty} (2\pi)^{-1} \int e^{-i(t-s)\xi} f^*(t-s) \sin(t\tau) \sin(s\tau) h^*(t/c) h^*(s/c) dt ds
\]

\[
= (f(a) + f(b)) \| h^*(t) \|^2 / 4,
\]

where \( \xi = (a + b)/2 \) and \( \tau = (b - a)/2 \). Since \( \int \sin(t(x - a)) k^*(t/c_n) \times (1 + t^2) dt = 0, \) by (45)

\[
EK_n^2(X, a) = (2\pi)^{-2} \int e^{-i(t-s)a} f^*(t-s)(1 + t^2)(1 + s^2)
\]

\[
\times k^*(t/c_n) k^*(s/c_n) dt ds
\]

\[
= (2\pi)^{-2} c_n^4 \int e^{-i(t-s)a} f^*(t-s)(t/c_n)^2 k^*(t/c_n)(s/c_n)^2
\]

\[
\times k^*(s/c_n) dt ds + o(c_n^5)
\]

\[
= (2\pi)^{-1} c_n^5 f(a; G) \| t^2 k^*(t) \|^2 + o(c_n^5).
\]
Set $h(x) = k'(x)$. By a similar argument $EI_2(X, a, b)$ is equal to

$$
\pi^{-2} \int e^{-i(t-s)x} \int \frac{\sin(\pi t)}{t} \frac{\sin(\pi s)}{s} (1+t^2)(1+s^2) \times k^*(t/c_n) k^*(s/c_n) \, dt \, ds
$$

$$
= \frac{c_n^2}{\pi} \int \int e^{-i(t-s)x} f^*(t-s) \sin(\pi t) \sin(\pi s) \times (t/c_n) k^*(t/c_n)(s/c_n) k^*(s/c_n) \, dt \, ds + o(c_n^3)
$$

$$
= \frac{2c_n^3}{\pi} \left( f(a; G) + f(b; G) \right) \|h^*(t)\|^2/4 + o(c_n^3)
$$

$$
= \frac{c_n^3}{2\pi} \left( f(a; G) + f(b; G) \right) \|h^*(t)\|^2 + o(c_n^3).
$$

Now let us prove (45) and (46). Let $u = t + s$ and $v = t - s$. Then

$$
(2\pi)^{-1} \int \int e^{-i(t-s)a} f^*(t-s) h^*(t/c) h^*(s/c) \, dt \, ds
$$

$$
= (2\pi)^{-1} \int \int e^{-ivb} f^*(v) h^*((u+v)/(2c)) h^*((v-u)/(2c)) \, du \, dv/2.
$$

Set $h_1(x) = (2\pi)h^2(x)$. Then $h^*_n(t) = \int h^*(t-s)h^*(s) \, ds$ and

$$
\int h^*((u+v)/(2c)) h^*((v-u)/(2c)) \, du
$$

$$
= 2c \int h^*(w) h^*(v/c - w) \, dw = 2ch^*_1(v/c),
$$

so that

$$
(c2\pi)^{-1} \int \int e^{-i(t-s)a} f^*(t-s) h^*(t/c) h^*(s/c) \, dt \, ds
$$

$$
= (2\pi)^{-1} \int e^{-ivb} f^*(v) h^*_1(v/c) \, dv
$$

$$
= \int f(a - x/c) h_1(x) \, dx = f(a) \int h_1(x) \, dx + o(1)
$$

$$
= f(a) h^*_1(0) + o(1) = f(a) \|h^*_1\|^2 + o(1).
$$
This proves (45). For (46) we have
\[
(2\pi)^{-1} \int e^{-i(t-s)\xi} f^*(t-s) \sin(t\tau) \sin(s\tau) h^*(t/c) h^*(s/c) \, dt \, ds
\]
\[
= (2\pi)^{-1} \int e^{-iv\xi} f^*(v) [\cos(v\tau) - \cos(u\tau)] h^*((u + v)/(2c))
\times h^*((v - u)/(2c)) \, dv \, du / 4.
\]
Since \(h^*(w)h^*(z-w), -\infty < z < \infty\) is uniformly continuous with support \([-1, 1]\), by the Riemann–Lebesgue lemma
\[
\sup_v \left| \int \cos(u\tau) h^*((u + v)/(2c)) h^*((v - u)/(2c)) \, dv \right|
= 2c \sup_v \left| \int \cos(\tau(2cw - v)) h^*(w) h^*(v/c - w) \, dw \right| = o(c),
\]
which implies that
\[
(2\pi)^{-1} \int e^{-i(t-s)\xi} f^*(t-s) \sin(t\tau) \sin(s\tau) h^*(t/c) h^*(s/c) \, dt \, ds
\]
\[
= (2\pi)^{-1} \int e^{-iv\xi} f^*(v) \cos(v\tau) h^+\tau(v/c) \, dv / 2 + o(1)
\]
\[
= (2\pi)^{-1} \int [e^{-iva} + e^{-ivb}] f^*(v) h^+\tau(v/c) \, dv / 4 + o(1)
\]
\[
= [f(a) + f(b)] \| h^* \|^2 / 4 + o(1).
\]

\[\square\]
